## Busbars and distribution

POWER GUIDE 2009 / BOOK 12

## INTRO

## Protection and control of operating circuits are the basic functions of a distribution panel. But upstream there is another function, possibly more discreet, but just as essential: distribution.

Even more than for the protection and control functions, the selection and setup of distribution equipment require an approach that combines selection of products (number of outputs, cross-sections, conductor types, connection method) and checking the operating conditions (current-carrying capacity, short circuits, isolation, etc.) in multiple configurations.

Depending on the power installed, distribution is carried out via distribution blocks (up to 400 A ) or via busbars ( 250 A to 4000 A ). The former must be selected according to their characteristics (see page 32), while the latter must be carefully calculated and sized according to requirements (see page 06).

# Distribution and standards 

Distribution can be defined as supplying power to a number of physically separate and individually protected circuits from a single circuit.

Depending on the circuits to be supplied, distribution will be via busbars (flat or C-section copper or aluminium bars, see p. 06), via prefabricated distribution blocks (power distribution blocks, modular distribution blocks, distribution terminal blocks, see p. 32) or via simple supply busbars. According to the standards, a device providing protection against short circuits and overloads must be placed at the point where a change of cross-section, type, installation method or composition leads to a reduction in the current-carrying capacity (IEC 60364-4-43).

${ }^{\wedge}$ Main busbar at the top of the enclosure with 2 copper bars per pole

[^0]If it were applied to the letter, this rule would lead to over-sizing of cross-sections for fault conditions. The standard therefore allows for there to be no protection device at the origin of the branch line subject to two conditions.

## Theoretical layout

$P_{1}$ protects $S_{1}$
$P_{2}$ protects $S_{2}$
There is no reduction in cross-section before $\mathrm{P}_{2}$

Upstream device $P_{1}$ effectively protects the branch line $S_{2} \ldots$
... or the branch line $\mathrm{S}_{2}$ is less than three metres long, is not installed near any combustible materials and every precaution has been taken to limit the risks of short circuits. There is no other tap-off or power socket on the branch line $\mathrm{S}_{2}$ upstream

Multi-level distribution

This layout can be used for example when several distribution blocks ( $2^{\text {nd }}$ level) are supplied from a single busbar ( $1^{\text {st }}$ level). If the sum of the currents tapped off at the first level ( $I_{1}, I_{2}$, etc.) is greater than It, a protection device $P_{2}$ must be provided on $S_{2}$.

< Modular distribution block

${ }^{\wedge}$ Distribution via supply busbars

## Distribution and standards (continued)

## STATUTORY CONDITIONS FOR PROTECTING BRANCH OR DISTRIBUTED LINES

## 1 SUMMARY OF THE GENERAL PRINCIPLE FOR CHECKING THERMAL STRESS

For insulated cables and conductors, the breaking time of any current resulting from a short circuit occurring at any point must not be longer than the time taken for the temperature of the conductors to reach their permissible limit.
This condition can be verified by checking that the thermal stress $\mathrm{K}^{2} \mathrm{~S}^{2}$ that the conductor can withstand is greater than the thermal stress (energy $\left.\right|^{2} t$ ) that the protection device allows to pass.

## 2 CHECKING THE PROTECTION CONDITIONS OF THE BRANCH LINE(S) WITH REGARD TO THE THERMAL STRESSES

For branch lines with smaller cross-sections $\left(S_{2}<S_{1}\right)$, check that the stress permitted by the branch line is actually greater than the energy limited by the main device $P_{1}$. The permissible thermal stress values $\mathrm{K}^{2} \mathrm{~S}^{2}$ can be easily calculated using the k values given in the table below:

The maximum energy values limited by the devices are given in the form of figures Ifor example 55,000 $A^{2}$ s for modular devices with ratings up to 32 A or in the form of limitation curves (see Book 5).

## 3 CHECKING THE PROTECTION CONDITIONS USING THE "TRIANGLE RULE"

The short-circuit protection device $P_{1}$ placed at the origin A of the line can be considered to effectively protect branch $\mathrm{S}_{2}$ as long as the length of the branch busbar system $\mathrm{S}_{2}$ does not exceed a certain length, which can be calculated using the triangle rule.

- The maximum length $L_{1}$ of the conductor with crosssection $\mathrm{S}_{1}$ corresponds to the portion of the circuit $A B$ that is protected against short circuits by protection device $P_{1}$ placed at point $A$.
- The maximum length $L_{2}$ of the conductor with crosssection $\mathrm{S}_{2}$ corresponds to the portion of the circuit AM that is protected against short circuits by protection device $P_{1}$ placed at point $A$.
These maximum lengths correspond to the minimum short circuit for which protection device $\mathrm{P}_{1}$ can operate (see Book 4).

| K values for conductors |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Property/Condition | Type of insulation of the conductor |  |  |  |  |  |  |  |
|  | PVC <br> Thermoplastic |  | PVC <br> Thermoplastic $90^{\circ} \mathrm{C}$ |  | EPR XLPE <br> Thermosetting | Rubber $60^{\circ} \mathrm{C}$ Thermosetting | Mineral |  |
| Conductor cross-sect. mm ${ }^{2}$ | $\leqslant 300$ | > 300 | $\leqslant 300$ | > 300 |  |  |  |  |
| Initial temperature ${ }^{\circ} \mathrm{C}$ | 70 |  | 90 |  | 90 | 60 | 70 | 105 |
| Final temperature ${ }^{\circ} \mathrm{C}$ | 160 | 140 | 160 | 140 | 250 | 200 | 160 | 250 |
| K values |  |  |  |  |  |  |  |  |
| Copper conductor | 115 | 103 | 100 | 86 | 143 | 141 | 115 | $\begin{array}{r} 135 \\ -115 \end{array}$ |
| Aluminium conductor | 76 | 68 | 66 | 57 | 94 | 93 | - | - |
| Connections soldered with tin solder for copper conductors | 115 | - | - | - | - | - | - | - |

$S_{1}$ corresponds to the cross-section of the main conductor and $S_{2}$ to the cross-section of the branch conductor.
The maximum length of the branch conductor with cross-section $\mathrm{S}_{2}$ that is protected against short circuits by protection device $P_{1}$ placed at point $A$ is represented by segment $O N$. It can be seen using this representation that the protected length of the branch line decreases the further away the tap-off point is from protection $P_{1}$, up to the prohibition of any $S_{2}$ smaller cross-section tap-off at the apex of the triangle, B.
This method can be applied to short-circuit protection devices and those providing protection against overloads respectively, as long as device $P_{2}$ effectively protects line $\mathrm{S}_{2}$ and there is no other tap-off between points $A$ and $O$.

## 43 METRE RULE APPLIED TO OVERLOAD PROTECTION DEVICES

When protection device $P_{1}$ placed at the head of line $S_{1}$ does not have any overload protection function or its characteristics are not compatible with the overload protection of the branch line $\mathrm{S}_{2}$ (very long circuits, significant reduction in cross-section), it is possible to move device $P_{2}$ up to 3 m from the origin ( 0 ) of the tap-off as long as there is no tap-off or power socket on this portion of busbar system and the risk of short circuit, fire and injury is reduced to the minimum for this portion (use of reinforced insulation conductors, sheathing, separation from hot and damaging parts).

## 5 EXEMPTION FROM PROTECTION AGAINST OVERLOADS

The diagram above illustrates three examples of tap-offs $\left(S_{1}, S_{2}, S_{3}\right)$ where it is possible not to provide any overload protection or simply not to check whether this condition is met.

- Busbar system $\mathrm{S}_{2}$ is effectively protected against overloads by $\mathrm{P}_{1}$ and the busbar system does not have any tap-offs or power sockets upstream of $P_{2}$
- Busbar system $S_{3}$ is not likely to have overload currents travelling over it and the busbar system does not have any tap-offs or power sockets upstream of $P_{3}$
- Busbar system $\mathrm{S}_{4}$ is intended for communication, control, signalling and similar type functions and the busbar system does not have any tap-offs or power sockets upstream of $P_{4}$.

## Sizing busbars

The busbar constitutes the real "backbone" of any distribution assembly. The main busbar and branch busbars supply and distribute the energy.

Busbars can be created using copper or aluminium bars. Flat copper bars are used for busbars up to 4000 A with Legrand supports. They provide great flexibility of use, but require machining on request (see p. 26). Legrand aluminium bars are made of C-section rails. Connection is carried out without drilling, using special hammer head screws.

They are used for busbars up to 1600 A, or 3200 A by doubling the supports and the bars.
The electrical and mechanical characteristics of Legrand busbar supports, and strict compliance with the maximum installation distances, ensure isolation between the poles and that the bars can resist the electrodynamic forces.

## DETERMINING THE USABLE CROSS-SECTION OF THE BARS

The required cross-section of the bars is determined according to the operating current, the protection index of the enclosure and after checking the shortcircuit thermal stress.
The currents are named in accordance with the definitions in standard IEC 60947-1 applied to the usual operating conditions for a temperature rise $\Delta t$ of the bars which does not exceed $65^{\circ} \mathrm{C}$.

< Temperature rise test for a $3 \times 120 \times 10$ per pole busbar on support Cat. No. 37454

## Currents according to standard IEC 60947-1

- le: rated operating current to be taken into consideration in enclosures with natural ventilation or in panels with IP $\leqslant 30$ protection index (ambient internal temperature $\leqslant 25^{\circ} \mathrm{C}$ ).
- Ithe: thermal current in enclosure corresponding to the most severe installation conditions. Sealed enclosures do not allow natural air change, as the IP protection index is greater than 30 lambient internal temperature $\leqslant 50^{\circ} \mathrm{C}$ ).

## Sizing busbars (continued)

## CHECKING THE PERMISSIBLE THERMAL STRESS

The thermal stress permitted by the bars must be greater than that limited by the protection device.

## Calculating the thermal stress

The maximum thermal stress value $I^{2} t$ taken into consideration for a short-circuit current of less than 5 s is calculated using the formula $\mathrm{I}^{2} \mathrm{t}=\mathrm{K}^{2} \mathrm{~S}^{2}$, where: - K = $115 \mathrm{As}^{0.5} / \mathrm{mm}^{2}$ for flexible copper bars (max. temperature: $160^{\circ} \mathrm{C}$ )

- $\mathrm{K}=135 \mathrm{As}^{0.5} / \mathrm{mm}^{2}$ for large cross-section rigid copper bars (width greater than 50 mm ; max. temperature: $200^{\circ} \mathrm{C}$ )
- $\mathrm{K}=143$ As ${ }^{0.5} / \mathrm{mm}^{2}$ for small cross-section rigid copper bars (width less than 50 mm ) and C-section bars (max. temperature: $\mathbf{2 2 0 ^ { \circ }} \mathrm{C}$ )
- $\mathrm{K}=91 \mathrm{As}{ }^{0.5} / \mathrm{mm}^{2}$ for rigid aluminium bars (max. temperature: $200^{\circ} \mathrm{C}$ )
- $\mathrm{S}=$ bar cross-section in $\mathrm{mm}^{2}$

The conventional value of the short-time withstand current with regard to thermal stress, in relation to a period of 1 s , is expressed by the formula: $\mathrm{Icw}_{1 \mathrm{~s}}=\sqrt{\mathrm{I}^{2} \mathrm{t}}$

Curve showing thermal stress limited by a DPX 250 ER ( 160 A)

Example: using a $12 \times 4 \mathrm{~mm}$ rigid flat bar for 160 A permissible $I^{2}$ t of the bar: $4.7 \times 10^{7} \mathrm{~A}^{2} \mathrm{~s}$
Prospective rms lk: $10 \mathrm{kA}\left(10^{4} \mathrm{~A}\right)$
The thermal stress limited by this device can then be read by plotting the above value on the limitation curve given for the protection device (in this case, a DPX 250 ER 160 A): $5 \times 10^{5} \mathrm{~A}^{2} \mathrm{~s}$, value less than the $I^{2} t$ permitted by the bar.

## DETERMINING THE DISTANCES BETWEEN SUPPORTS

The distance between the supports is determined according to the electrodynamic stress generated by the short circuit.
The forces exerted between the bars during a short circuit are proportional to the peak value of the shortcircuit current.

## 1 RMS VALUE OF THE PROSPECTIVE SHORT-CIRCUIT CURRENT (Ik)

This is the prospective maximum value of the current which would circulate during a short circuit if there were no protection device. It depends on the type and power of the source. The actual short-circuit current will generally be lower in view of the impedance of the busbar system. The calculation of the values to be taken into account is described in Book 4: "Sizing conductors and selecting protection devices".

## Prospective Ik

This is the rms value of the short-circuit current that would circulate if there were no protection device. lk1: between phase and neutral
lk2: between 2 phases
lk3: between 3 phases
These values were formerly called $\mathrm{Isc}_{1}, \mathrm{Isc}_{2}$ and $\mathrm{Isc}_{3}$. Do not confuse Ik with Ipk, which is defined below.

If in doubt or the actual prospective lk value is not known, use a value of at least $20 \times \mathrm{In}$.

## 2 PEAK CURRENT VALUE (Ipk)

The limited peak current is determined from the characteristics of the protection device (see Book 5: "Breaking and protection devices").
It represents the maximum (peak) value limited by this device. If there is no limiting protection device, the prospective peak value can be calculated from the prospective short-circuit current and an asymmetry coefficient (see next page).

The electrodynamic forces are proportional to the square of the peak current. It is this value which must be taken into consideration when determining the distances between the supports.

## Sizing busbars (continued)

## Limiting protection device

The limitation curves of the protection devices (DX and DPX) give the limited peak current according to the prospective short-circuit current (see Book 5 "Breaking and protection devices").
The non-limited peak Ik curve corresponds to no protection.

The table below gives the limited peak value (lpk) directly for the maximum prospective short-circuit value equal to the breaking capacity (Icu) of the device.
For lower prospective short-circuit values, reading the curves will provide an optimised value.

| Device | Rating <br> $(\mathbf{A})$ | Ipk (peak) max. <br> $(\mathrm{kA})$ |
| :--- | :---: | :---: |
| DPX 125 | $16-25$ | 11.9 |
| DPX 125 | $40-63$ | 15 |
| DPX 125 | $100-125$ | 17 |
| DPX 160 | 25 | 14.3 |
| DPX 160 | 40 to 160 | 20 |
| DPX 250 ER | 100 to 250 | 22 |
| DPX 250 | 40 to 250 | 27 |
| DPX-H 250 | 40 to 250 | 34 |
| DPX 630 | 250 to 630 | 34 |
| DPX-H 630 | 250 to 630 | 42 |
| DPX 1600 | 630 to 1600 | 85 |
| DPX-H 1600 | 630 to 1600 | 110 |

## Non-limiting protection device

When the busbar is protected by a non-limiting protection device (for example $\mathrm{DMX}^{3}$ ), the maximum value of the peak current is developed during the first half-period of the short circuit. This is referred to as the asymmetric $1^{\text {st }}$ peak.

The relationship between the peak value and the rms value of the prospective short-circuit current is defined by the coefficient of asymmetry n :

Ipk (peak) = $\mathbf{n} \times$ prospective rms lk

| Prospective rms Ik | n |
| :---: | :---: |
| (kA) |  |
| Ik $\leqslant 5$ | 1.5 |
| $5<$ Ik $\leqslant 10$ | 1.7 |
| $10<I k \leqslant 20$ | 2 |
| $20<I k \leqslant 50$ | 2.1 |
| $50<I k$ | 2.2 |

The electrodynamic forces that are exerted between conductors, in particular in busbars, are the result of the interaction of the magnetic fields produced by the current flowing through them. These forces are proportional to the square of the peak current intensity that can be recorded in Â or $k \hat{A}$. When there is a short circuit, these forces can become considerable (several hundred daN) and cause deformation of the bars or breaking of the supports. The calculation of the forces, prior to the tests, is the result of applying Laplace's law, which states that when a conductor through which a current ${ }_{1} 1$ passes is placed in a magnẹtic field H with induction B , each individual element $d l$ of this conductor is subjected to a force of $d F=i d l \wedge B$.
If the magnetic field originates from another conductor through which $i_{2}$ passes, there is then an interaction of each of the fields $\vec{H}_{1}$ and $\vec{H}_{2}$ and forces $\vec{F}_{1}$ and $\vec{F}_{2}$ generated by $B_{1}$ and $B_{2}$.

The directions of the vectors are given by Ampère's law.
If currents $\mathrm{i}_{1}$ and $\mathrm{i}_{2}$ circulate in the same direction, they attract, if they circulate in opposite directions, they repel.

${ }^{\wedge}$ Schematic representation at a point in space (Biot-Savart law)

## General formula for calculating the forces in the event of a short circuit

The calculation of the forces in the event of short circuits (Fmax), can be defined as follows:

D: length of the conductor (distance between supports in the case of bars)

E: spacing between conductors
$F_{\max }=2 \times I^{2} \times \frac{D}{E} \times 10^{-8}$ with $F$ in daN, $I$ in $A$ peak, and $D$ and $E$ in the same unit.
In practice, this formula is only applicable to very long ( $D>20 \mathrm{E}$ ) round conductors. When D is shorter, a correction, called the "end factor" is applied:

- For $4 \leqslant \frac{D}{E}<20$, use $F_{\max }=2 \times 1^{2} \times\left(\frac{D}{E}-1\right) \times 10^{-8}$
- For $\frac{D}{E}<4$, use $F_{\max }=2 \times I^{2} \times\left[\sqrt{\left(\frac{D}{E}\right)^{2}+1}-1\right] \times 10^{-8}$

Correction factors must be inserted in these formulae to take account of the layout and shape of the conductors when they are not round.

## Sizing busbars (continued)

## 3 PRACTICAL DETERMINATION OF THE DISTANCES BETWEEN THE SUPPORTS ACCORDING TO THE PEAK CURRENT (lpk)

The following tables can be used to determine the maximum distances D (in mm ) between the supports, based on the required Ipk value, and thus create busbars.
 The shorter the distance between the supports, the higher the permissible Ik. With single pole supports, it is also possible to vary the spacing between bars E . The wider the spacing between bars, the higher the permissible lk.
Distance D' after the last support must always be less than $30 \%$ of distance $D$.

## The Ipk values to be taken into account must be determined according to the limitation curves for the devices (see p. 12)

The distances take the most severe short-circuit conditions into account:

- Ik $\mathbf{k}_{2}$ two-phase short-circuit value resulting in non-uniform forces
- $\mathrm{Ik}_{3}$ three-phase short-circuit value resulting in maximum force on the central bar
- I $\mathbf{k}_{1}$ value (phase/neutral) is generally the weakest

< Cables are connected to C -section aluminium bars without drilling, using hammer head screws

## MAGNETIC EFFECTS ASSOCIATED WITH BUSBARS

The magnetic effects can be divided into transient effects, which are the short-circuit electrodynamic forces, and permanent effects created by induction due to circulation of high currents. The effects of induction have several consequences:

- Increased impedance in the conductors due to the effects of mutual inductance
- Temperature rise linked to magnetic saturation of the materials in the fields formed around the conductors
- Possible interference in sensitive devices for which it is recommended that minimum cohabitation distances are observed (see Book 8)

## Measuring the magnetic field lines around a busbar

${ }^{\wedge}$ A knowledge of the induction phenomena generated by the power conductors enables appropriate mounting and cohabitation conditions to be stipulated.

Magnetic field values are generally expressed using two units:

- The tesla (T) represents the magnetic induction value, which, directed perpendicular to a $1 \mathrm{~m}^{2}$ surface, produces a flux of 1 weber across this surface. As the tesla expresses a very high value, its sub-units are generally used: the millitesla ( mT ) and the microtesla ( $\mu \mathrm{T}$ ). The old unit, the gauss ( G ) should not be used ( $1 \mathrm{~T}=10,000 \mathrm{G}$ ).
- The ampere per metre ( $\mathrm{A} / \mathrm{m}$ ), a non-SI unit, formerly called the "ampere-turn per metre", indicates the intensity of the magnetic field created at the centre of a 1 m diameter circular circuit crossed by a constant 1 A current.
The induction B (in T ) and the field H (in $\mathrm{A} / \mathrm{m}$ ) are linked by the formula:
$B=\mu_{0} \mu_{\mathrm{r}} \mathrm{H}$ where:
- $\mu_{0}=4 \pi 10^{-7}$ (magnetic permeability of air or the vacuum)
- $\mu_{r}=1$ (relative permeability of iron)
giving: $1 \mu \mathrm{~T}=1.25 \mathrm{~A} / \mathrm{m}$ and $1 \mathrm{~A} / \mathrm{m}=0.8 \mu \mathrm{~T}$
The recommended mounting distances correspond to magnetic field values read close to a busbar at 4000 A :
$0.1 \mathrm{mT}(125 \mathrm{~A} / \mathrm{m})$ at a distance of 1 m (sensitive equipment)
$0.5 \mathrm{mT}(625 \mathrm{~A} / \mathrm{m})$ at a distance of 50 cm (limited sensitivity equipment)
$1 \mathrm{mT}(1250 \mathrm{~A} / \mathrm{m})$ at a distance of 30 cm (very low sensitivity equipment)

The formation of magnetic fields around high power busbars MUST be prevented.
The structures of $\mathrm{XL}^{3}$ enclosures, which incorporate non-magnetic elements (which create air gaps), are ideal for the highest currents.

${ }^{\wedge}$ The corner pieces of $\mathrm{XL}^{3} 4000$ enclosures are made of non-magnetic alloy

The specified separation distances between conductors and devices will be increased in the event of cohabitation with very high power busbars (up to 4000 A ).
If there are no instructions from the manufacturers, the minimum distances will be increased to:
-30 cm for devices with very low sensitivity (fuses, non residual current devices, connections, MCCBs, etc.)
-50 cm for devices with limited sensitivity (secondary circuit breakers, including RCDs, relays, contactors, transformers, etc.)

- 1 m for sensitive devices (electronics and digital measuring devices, bus-based systems, remote controls, electronic switches, etc.)
- Devices which are very sensitive to magnetic fields lanalogue gauge, meters, oscillographs, cathode ray tubes, etc.) may require greater separation distances.

## Sizing busbars (continued)

The circulation of high currents in busbars leads to the induction of magnetic fields in the surrounding exposed metal conductive parts lenclosure panels,
frames and chassis, etc.).
The phenomenon is similar to that used for creating electromagnetic shielding, but in this case it must be limited to avoid temperature rises in these exposed conductive parts and
 the circulation of induced currents.

Minimum distances between bars and metal panels

Induction is higher facing the flat surface of bars (distance X ).
Above 2500 A, maintain minimum distances: $X \geqslant 150 \mathrm{~mm}$ and $Y \geqslant 100 \mathrm{~mm}$.

In practice the values of the magnetic fields generated by the power bars considerably exceed the standard values for exposure of the devices.
Much more severe tests, such as those to undergone by Lexic range devices, are therefore essential to ensure they will operate correctly in these conditions.

${ }^{\wedge}$ Supports on aluminium crosspieces to prevent the formation of magnetic fields.

^ Non-magnetic stainless steel screws perform the same function on supports Cat. No. 37324

## CHECKING THE INSULATION CHARACTERISTICS

## 1 Insulation voltage ui

This must be the same as or higher than the maximum value of the rated operating voltage for the assembly, or the reference voltage. The latter depends on the mains supply voltage and the structure of the source (star, delta, with or without neutral).

## Reference voltage values (in $V$ ) to be taken into consideration according to the nominal supply voltage

| Nominal power supply voltage | For insulation between phases | For insulation between phase and neutral |  |
| :---: | :---: | :---: | :---: |
|  | All supplies | 4-wire three phase supplies neutral connected to earth | 3 -wire three phase supplies not connected to earth or one phase connected to earth |
| 60 | 63 | 32 | 63 |
| 110-120-127 | 125 | 80 | 125 |
| 160 | 160 | - | 160 |
| 208 | 200 | 125 | 200 |
| 220-230-240 | 250 | 160 | 250 |
| 300 | 320 | - | 320 |
| 380-400-415 | 400 | 250 | 400 |
| 440 | 500 | 250 | 500 |
| 480-500 | 500 | 320 | 500 |
| 575 | 630 | 400 | 680 |
| 600 | 630 | - | 630 |
| 660-690 | 630 | 400 | 630 |
| 720-830 | 800 | 500 | 800 |
| 960 | 1000 | 630 | 1000 |
| 1000 | 1000 | - | 1000 |

A check must be carried out to ensure that the reference voltage is not higher than the insulation voltage Ui of the devices, busbars and distribution blocks.

The insulation between live conductors and the earth of the Legrand busbar supports and distribution blocks is at least equal to that between phases. The insulation value Ui can be used for all mains supplies.

## Sizing busbars (continued)

## 2 IMPULSE WITHSTAND VOLTAGE Uimp

This value characterises the permissible overvoltage level in the form of a voltage wave representative of a lightning strike.
Its value (in kV ) depends on the mains voltage, and also the location in the installation.
It is highest at the origin of the installation (upstream of the incoming MCB or the transformer).
Equipment can be designated or marked according to two methods.

- Two values indicated (example: 230/400 V): these refer to a 4 -wire three-phase supply (star configuration). The lower value is the voltage between phase and neutral, and the higher is the value between phases.
- A single value indicated (example: 400 V ): this normally refers to a 3-wire single phase or three phase supply with no earth connection (or with one phase connected to earth) and for which the phaseearth voltage must be considered capable of reaching the value of the phase-to-phase voltage (full voltage between phases).

All the specifications relating to insulation are defined by international standard IEC 60664-1 "Insulation coordination in low-voltage systems (networks)". They are also contained in standards IEC 60439-1 and IEC 60947-1.

Impulse voltage values to be taken into consideration according to the voltage in relation to earth and location in the installation

| Maximum rated operating voltage value in relation to earth (rms or DC value) | Preferred rated impulse withstand voltage values (1.2/50 $\mu \mathrm{s}$ ) at 2000 m (in kV) |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | To be considered generally |  |  |  | Can be considered for underground power supplies |  |  |  |
|  | Overvoltage category |  |  |  | Overvoltage category |  |  |  |
|  | ı | III | 11 | 1 | Iv | III | 11 | 1 |
|  | Installation origin level | Distribution level | Load level (devices, equipment) | Specially protected level | Installation origin level | Distribution level | Load level (devices, equipment) | Specially protected level |
| 50 | 51.5 | 0.8 | 0.5 | 0.33 | 0.8 | 0.5 | 0.33 | - |
| 100 | 2.5 | 1.5 | 0.8 | 0.5 | 1.5 | 0.8 | 0.5 | 0.33 |
| 150 | 4 | 2.5 | 1.5 | 0.8 | 2.5 | 1.5 | 0.8 | 0.5 |
| 300 | 6 | 4 | 2.5 | 1.5 | 4 | 2.5 | 1.5 | 0.8 |
| 600 | 8 | 6 | 4 | 2.5 | 6 | 4 | 2.5 | 1.5 |
| 1000 | 12 | 8 | 6 | 4 | 8 | 6 | 4 | 2.5 |

NB: The impulse withstand voltage given for an altitude of 2000 m implies that tests are carried out at higher values at sea level: 7.4 kV for $6 \mathrm{kV}-9.8 \mathrm{kV}$ for $8 \mathrm{kV}-14.8 \mathrm{kV}$ for 12 kV .

## Design of the isolating supports for busbars and distribution blocks

The insulation voltage Ui of supports and distribution blocks is determined by measuring the creepage distances, by the insulating properties of the material and by the degree of pollution.

- The creepage distance is the distance measured on the surface of the insulation in the most unfavourable conditions or positions between the live parts (phases, phases and neutral) and between these parts and the exposed conductive part.
- The insulating properties of the material are characterised amongst other things by the comparative tracking index (CTI). The higher this value, the less the insulation will be damaged by conductive pollution deposits (Legrand busbar supports, made of fibreglass reinforced polyamide 6.6, have an index of more than 400).
- The degree of pollution characterises the risk of conductive pollution deposits, using a number from 1 to 4:
- 1 : No pollution
- 2 : No pollution and temporary condensation
- 3 : Conductive pollution possible
- 4 : Persistent pollution

Level 2 is similar to household, commercial and residential applications
Level 3 is similar to industrial applications

A. Conductive elements
B. Screen
C. Distance in air or clearance
D. Creepage distance
${ }^{\wedge}$ General principle of measuring the clearances and creepage distances

## Shaping and connecting bars

Creating busbars generally involves machining, bending and shaping which require a high degree of expertise to avoid weakening the bars or creating stray stresses. The same applies to connections between bars, whose quality depends on the sizes and conditions of the contact areas, and the pressure of this contact (number of screws and effectiveness of tightening).

## RIGID BARS

## 1 SIZES OF THE CONTACT AREAS

The contact area (Sc) must be at least 5 times the crosssection of the bar (Sb). Sc > $5 \times \mathrm{Sb}$ For main busbar
 continuity links, it is advisable to establish contacts along the entire length of the bar in order to ensure optimum heat transfer.

For branch busbars, the contact area can be smaller, complying with the condition $\mathrm{Sc}>5 \times \mathrm{Sb}$. For equipment connection plates, contact must be made over the whole surface of the plate for use at nominal current.

## 2 contact pressure

The contact pressure between bars is provided using screws whose size, quality, number and tightening torque are selected according to the current and the sizes of the bars.
Too high a tightening torque or not enough screws can lead to distortions which reduce the contact area. It is therefore advisable to distribute the pressure by increasing the number of tightening points and using wide washers or back-plates.

${ }^{\wedge}$ Applying a mark (paint, brittle coating) will show any loosening and can also be used to check that tightening has been carried out correctly (tell-tale)

Recommended screws and minimum characteristics

| I (A) |  | Bar width (mm) | Number of screws | $\begin{aligned} & \emptyset \text { Screw } \\ & (\mathrm{mm}) \end{aligned}$ | Minimum quantity | Tightening torque ( Nm ) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 bar | 2+ bars |  |  |  |  |  |
| $\leqslant 250$ | - | $\leqslant 25$ | $\begin{aligned} & 1 \\ & 2 \end{aligned}$ | $\begin{aligned} & \text { M8 } \\ & \text { M6 } \end{aligned}$ | $\begin{aligned} & \hline 8-8 \\ & 8-8 \end{aligned}$ | $\begin{aligned} & 15 / 20 \\ & 10 / 15 \end{aligned}$ |
| $\leqslant 400$ | - | $\leqslant 32$ | 1 | M10 | 6-8 | 30/35 |
| $\leqslant 630$ | - | $\leqslant 50$ | $\begin{aligned} & 1 \\ & 2 \\ & 2 \\ & \hline \end{aligned}$ | $\begin{aligned} & \text { M12 } \\ & \text { M10 } \\ & \text { M8 } \\ & \hline \end{aligned}$ | $\begin{aligned} & 6-8 \\ & 6-8 \\ & 8-8 \\ & \hline \end{aligned}$ | $\begin{aligned} & 50 / 60 \\ & 30 / 35 \\ & 15 / 20 \\ & \hline \end{aligned}$ |
| 800 | 1250 | $\leqslant 80$ | $\begin{aligned} & 4 \\ & 4 \end{aligned}$ | $\begin{aligned} & \text { M8 } \\ & \text { M10 } \end{aligned}$ | $\begin{aligned} & 8-8 \\ & 6-8 \end{aligned}$ | $\begin{aligned} & 15 / 20 \\ & 30 / 35 \end{aligned}$ |
| 1000 | 1600 | $\leqslant 100$ | $\begin{aligned} & 4 \\ & 2 \end{aligned}$ | $\begin{aligned} & \text { M10 } \\ & \text { M12 } \end{aligned}$ | $\begin{aligned} & 6-8 \\ & 6-8 \end{aligned}$ | $\begin{aligned} & 30 / 35 \\ & 50 / 60 \end{aligned}$ |
| 1600 | 2500 | $\leqslant 125$ | 4 | M12 | 6-8 | 50/60 |

Tightening torques that are too high lead to the limit of elasticity of the bolts being exceeded and creeping of the copper.

${ }^{\wedge}$ Connection on $120 \times 10$ bars (4000 A)

${ }^{\wedge}$ Double connection: $100 \times 10$ bars ( 3200 A ) and $80 \times 10$ bars ( 2500 A ) on common $120 \times 10$ bars

## C-section aluminium bars

The lugs or flexible bars connect directly with no need to add washers or spacers

## Shaping and connecting bars (continued)

## 3 CONDITION OF THE CONTACT AREAS

Apart from pronounced oxidation Isignificant blackening or presence of copper carbonate or "verdigris"), bars do not require any special preparation. Cleaning with acidified water is prohibited, as, apart from the risks, it requires neutralisation and rinsing. Surface sanding (240/400 grain) can be carried out, complying with the direction of sanding so that the "scratches" on bars that are in contact are perpendicular.

## MACHINING COPPER BARS

Copper is a soft, "greasy" or "sticky" metal in terms used in the trade. Shaping is generally carried out dry, but lubrication is necessary for high-speed cutting or drilling operations (up to $50 \mathrm{~m} / \mathrm{mn}$ ).

${ }^{\wedge}$ Sawing ( 8 D medium tooth) in a clamping vice

${ }^{\wedge}$ It is possible to make holes with drills for steel, but it is preferable to use special drills (with elongated flutes for easy detachment of chips)

^ The hydraulic punch is used to make precision holes easily ... and with no chips

## 5 bending bars

It is strongly recommended that a full-scale drawing is made of the bars, in particular for bends and stacking of bars.

The bars are separated by their thickness "e". The total centre line length before bending is the sum of the straight parts ( $\mathrm{L} 1+\mathrm{L} 2$ ) that are not subject to any distortion and the length $\ell$ of the curved elements on the neutral line lin theory at the centre of the thickness of the metal).

${ }^{\wedge}$ Creating a twist. The length $L$ of the twist is at least twice the width l of the bar

< Example of bending three bars one on top of the other to create power sockets

The calculation must be carried out based on the tool used and its actual bending radius $r$.

Bending on bending machine: $r=1$ to $2 e$

Bending on V-block: $r \min .=e$

Bending a 10 mm thick copper bar on a portable hydraulic tool

## Shaping and connecting bars (continued)

## FLEXIBLE BARS

Flexible bars can be used for making connections on devices or for creating links that can be adapted to virtually any requirement. Guaranteeing safety and high quality finish, they provide an undeniably attractive touch.
Based on the most commonly used sizes and the electrical capacities of the usual nominal values, the Legrand range of flexible bars is suitable for most connection or linking requirements.
As with any conductor, the current-carrying capacities of flexible bars may vary according to the conditions of use:

- Ambient temperature (actual in enclosure)
- Period of use (continuous or cyclic load), or installation conditions
- Bars on their own or grouped together (side by side in contact or with spacers)
- Ventilation: natural (IP $\leqslant 30$ ), forced (fan) or none (IP > 30)
- Vertical or horizontal routing.

The considerable variability of all these conditions leads to very different current-carrying capacities (in a ratio of 1 to 2 , or even more).

Flexible bars have higher current-carrying capacities than cables or rigid bars with the same cross-section due to their lamellar structure (limitation of eddy currents), their shape (better heat dissipation) and their permissible temperature $\left(105^{\circ} \mathrm{C}\right.$ high temperature PVC insulation).

Incorrect use can result in temperature rises that are incompatible with the insulation, disturbance or even damage to connected or surrounding equipment. Flexible bars are shaped manually without the need for any special tools, although some dexterity is required to achieve a perfect finish.

The currents le (A) and Ithe (A) of Legrand flexible bars are given for the following conditions:

- le (IP $\leqslant 30$ ): maximum permanent cur-rent-carrying capacity in open or ventilated enclosures, the positions of the bars and relative distance between them allow correct cooling.
The temperature in the enclosure must be similar to the ambient temperature.
- Ithe (IP > 30): maximum permanent currentcarrying capacity in sealed enclosures.
The bars can be installed close to one another, but must not be in contact.
The temperature in the enclosure can reach $50^{\circ} \mathrm{C}$.

< Connection of a DPX to a distribution block using flexible bars

## CURRENT TRANSFORMERS (CT)

Measuring devices such as ammeters, electricity meters and multifunction control units are connected via current transformers which provide a current of between 0 and 5 A . The transformation ratio will be chosen according to the maximum current to be measured.
These transformers can be fixed directly on flat, flexible or rigid bars.

$\wedge$ Fixing CTs on busbars

## Distribution blocks

The distribution block is a prefabricated device. It is therefore sized to suit its rated current and, unlike busbars, does not require manufacturing definitions. However, the diversity of distribution blocks according to their capacity, their connection mode and their installation calls for careful selection while adhering to precise standards.

| Possible locations for distribution blocks |  |  |  |
| :---: | :---: | :---: | :---: |
| Location |  | Example of Legrand solution |  |
| At panel supply end or output for connecting incoming or outgoing conductors |  | Connection boxes |  |
| Directly at the output of an upstream device |  | Distribution terminals |  |
| Directly at the input of downstream devices |  | Supply busbars |  |
| Independently of the upstream and downstream devices with the need to connect the input and outputs |  | Modular distribution blocks |  |

When a change of conductor cross-section or type results in a reduction of the current-carrying capacity, standard IEC 60364-473 stipulates that a protection device must be placed at this point. In certain conditions, it is however possible to depart from this rule (see p. 03)

## CHARACTERISTICS OF DISTRIBUTION BLOCKS

Before making the final choice of product, a few essential characteristics must be checked. These are given for all Legrand distribution blocks.

## 1 RATED CURRENT

Often called nominal current (In), this should be chosen according to the current of the upstream device or the cross-section of the power supply conductor.
As a general rule, use a distribution block with the same current as or immediately above that of the main device $\left(I_{t}\right)$, ensuring that the sum of the currents of the distributed circuits is not higher than the nominal current (In) of the distribution block.

125 A modular distribution
block equipped with an additional neutral terminal block >

# Distribution blocks (continued) 

## 2 PERMISSIBLE SHORT-CIRCUIT VALUE

- Value Icw characterises the conventional currentcarrying capacity for 1 s from the point of view of thermal stress.
- Value Ipk characterises the maximum peak current permitted by the distribution block. This value must be higher than that limited by the upstream protection device for the prospective short circuit.

## 3 INSULATION VALUE

- The insulation voltage Ui must be at least equal to the maximum value of the rated operating voltage of the assembly, or the reference voltage (see p. 23).
- The impulse withstand voltage Uimp characterises the permissible overvoltage level when there is a lightning strike (see p. 24).

Legrand distribution blocks are designed to resist thermal stress at least as high as that of the conductor with the cross-section corresponding to the nominal current, which means that no other checks are usually necessary.
They are tested for the harshest operating conditions corresponding to the highest overvoltage risks.
The Uimp value characterises this safety requirement.

It is not generally necessary to check the Ipk when the distribution block is protected by a device with the same nominal current. However it must be checked if the rating of the upstream device is higher than the current of the distribution block.

## Concern for maximum safety

Legrand distribution blocks are designed to minimise the risks of short circuits between poles: individual insulation of the bars on modular distribution blocks, partitioning of power distribution blocks, new totally isolated concept of single pole distribution blocks Cat. Nos. 048 71/73/83, all innovations to increase safety. Providing the highest level of fire resistance $1960^{\circ} \mathrm{C}$ incandescent wire in accordance with standard IEC 60695-2-1), Legrand distribution blocks meet the standard requirement for non-proximity of combustible materials.

< 160 A modular distribution block Cat. No. 048 87: total insulation of each pol

## 4 CONNECTION METHOD

### 4.1. Direct connection

The conductors are connected directly in the terminals without any special preparation. This is the preferred on-site method for H07 V-U, H07 V-R rigid conductors and FR-N05 VV-U and FR-N05 VV-R cables. Use of a ferrule (such as Starfix ${ }^{\top \mathrm{M}}$ ) is recommended for flexible conductors (H07 V-K) connected in butt terminals lunder the body of the screw) and for external flexible cables (H07 RN-F, A05 RR-F, etc.) which may be subject to pulling.

### 4.2. Connection via terminals

This type of connection is normally used for large cross-section conductors, and mainly for panels that are wired in the factory. It is characterised by excellent mechanical withstand, excellent electrical reliability and its ease of connection/disconnection.

63/100 A terminal blocks, 125/160 A modular distribution blocks and 250 A Lexiclic distribution blocks can be connected directly. 125/250 A extra-flat distribution blocks and 125/400 A stepped distribution blocks are connected via terminals.

Lexic modular distribution blocks for totally "universal" use >

## Distribution blocks (continued)

## PHASE BALANCING

A well-designed installation should never require rebalancing after it has been built. However, there are always unforeseen circumstances:

- The loads may not have been correctly identified luses on power sockets)
- The loads may be irregular, or even random: holiday homes, office blocks, etc.
Three-phase loads connected with motive power, heating, air conditioning, furnaces and in general any uses with a direct three-phase supply do not generate any significant unbalance.
However, all household applications (lighting, heating, domestic appliances) and office applications (computers, coffee machines, etc.) represent single phase loads that must be balanced.

Row of single phase outputs supplied via a DPX 125 (100 A)

Phase 1 supplies: 2 DX 32 A, 2 DX 20 A, 1 DX 10 A
Phase 2 supplies: 1 DX 32 A, 2 DX 20 A, 3 DX 10 A
Phase 3 supplies: 1 DX 32 A, 3 DX 20 A, 1 DX 10 A

The neutral conductor must be the same cross-section as the phase conductors:

- In single phase circuits, regardless of the cross-section, and in polyphase circuits up to a phase conductor cross-section of $16 \mathrm{~mm}^{2}$ for copper ( $25 \mathrm{~mm}^{2}$ for aluminium)
- Above this, its cross-section can be reduced in line with the load, unbalance, short-circuit thermal stress and harmonic conditions (see Book 4: "Sizing conductors and selecting protection devices").

## Breaking of the neutral

If the neutral breaks (maximum unbalance), the neutral point moves according to the load of each phase. The greater the load on a phase (phase 1 in this diagram), the lower its impedance. $\mathrm{V}_{1}$ drops, $\mathrm{V}_{2}$ and $\mathrm{V}_{3}$ increase and may reach the value of the phase-to-phase voltage on the phases with the lowest loads, which generally supply the most sensitive devices.

## Currents and voltages in star configuration three-phase system

In balanced system
$Z_{1}=Z_{2}=Z_{3}$
$I_{1}=I_{2}=I_{3}$
$l_{1}+I_{2}+I_{3}=0$ $\vec{v}_{1}=\vec{v}_{2}=\vec{v}_{3}=\vec{v}$
$\overrightarrow{\mathrm{v}}_{1}, \overrightarrow{\mathrm{v}}_{2}, \overrightarrow{\mathrm{v}}_{3}$ : Phase-to-neutral voltages $\mathrm{U}_{12}, \mathrm{U}_{23}, \mathrm{U}_{31}$ : Phase-to-phase voltages $\vec{U}_{12}=\vec{V}_{1}-\vec{V}_{2}$ $\overrightarrow{\mathrm{U}_{23}}=\overrightarrow{\mathrm{v}_{2}}-\overrightarrow{v_{3}}$ $\overrightarrow{\mathrm{U}_{31}}=\overrightarrow{\mathrm{v}}_{3}-\overrightarrow{\mathrm{v}}_{1}$

$$
U=v \times \sqrt{3}
$$

$$
(400=230 \times \sqrt{3})
$$

$$
(230=127 \times \sqrt{3})
$$

In unbalanced system with neutral
$\mathrm{Z}_{1} \neq \mathrm{Z}_{2} \neq \mathrm{Z}_{3}$
$I_{1} \neq I_{2} \neq I_{3}$
$I_{1}+I_{2}+I_{3}=$ In
$\vec{V}_{1}=\vec{V}_{2}=\vec{V}_{3}=\vec{V}$
The phase-to-neutral voltages remain balanced.
The neutral conductor maintains the balance of the phase-to-neutral voltages V by discharging the current due to the unbalance of the loads. It also discharges the current resulting from the presence of harmonics.

In unbalanced system without neutral
$\mathrm{Z}_{1} \neq \mathrm{Z}_{2} \neq \mathrm{Z}_{3}$
$l_{1} \neq I_{2} \neq I_{3}$
$I_{1}+I_{2}+I_{3}=0$
$\vec{v}_{1} \neq \vec{v}_{2} \neq \vec{v}_{3}$
The phase-to-neutral voltages V are unbalanced even though the phase-to-phase voltages U remain equal.

## Distribution blocks (continued)

## Currents and voltages in delta configuration three-phase system

## Balanced delta configuration

$\mathrm{Z}_{1}=\mathrm{Z}_{2}=\mathrm{Z}_{3}$
$\mathrm{J}_{1}=\mathrm{J}_{2}=\mathrm{J}_{3}$
$I_{1}=I_{2}=I_{3}=0$

Unbalanced delta configuration

$$
\begin{aligned}
& \mathrm{Z}_{1}=\mathrm{Z}_{2}=\mathrm{Z}_{3} \\
& \mathrm{~J}_{1}=\mathrm{J}_{2}=\mathrm{J}_{3} \\
& \mathrm{I}_{1}=\mathrm{I}_{2}=\mathrm{I}_{3} \text { but } \overrightarrow{\mathrm{I}_{1}}=\overrightarrow{\mathrm{I}_{2}}=\overrightarrow{\mathrm{I}_{3}}=0
\end{aligned}
$$

J: phase-to-neutral current I: phase-to-phase current
$\overrightarrow{I_{1}}=\overrightarrow{J_{1}}-\overrightarrow{J_{3}}$
$\overrightarrow{\mathrm{I}_{2}}=\overrightarrow{\mathrm{J}_{2}}-\overrightarrow{\mathrm{J}_{1}}$
$\overrightarrow{J_{3}}=\overrightarrow{J_{3}}-\overrightarrow{J_{2}}$
$\mathrm{I}=\mathrm{J} \times \sqrt{3}$

Unbalance does not have any consequences on the voltage in delta configurations, but the balance of the currents remains necessary to avoid line overcurrents (one phase overloaded) and limit inherent voltage drops.

In three-phase installations, the various circuits should be distributed on each phase, taking into account their power, their load factor (ratio of the actual power consumption to the nominal power), their operating factor (ratio of the operating time and the stoppage time to be weighted with the operating schedules) and their coincidence factor (ratio of the load of the circuits operating simultaneously to the maximum load of all of these circuits).
See Book 2 "Power balance and choice of power supply solutions".
Distribution optimises the energy management.

The maximum number of lighting points or socket outlets supplied by one circuit is 8 . Special or high power circuits (water heater, oven, washing machine) must be provided for this use only.
The maximum number of heaters must be appropriate for continuity of service.

## Cable cross-sections and ratings of protection devices according to circuits

Care must be taken to maintain the minimum required cross-sections during balancing operations: each circuit must remain protected by the recommended device.

| 230 V single phase circuit | Copper cross- <br> section (mm |  |  |
| :--- | :---: | :---: | :---: |
| Signalling | $0.75 / 1$ | Fuse rating <br> (A) | Circuit-breaker <br> rating(A) |
| Lighting | 1.5 | 2 | 6 |
| 16 A power socket | 8 max. <br> 5 max. | 2.5 | 10 |
| Water heater | 1.5 | 16 | 16 |
| Washing machine/tumble dryer/oven, | 2.5 | 16 | 16 |
| etc. | 2.5 | 16 | 20 |
| Cooking appliance | single phase |  |  |
| three-phase |  |  |  |

Legrand electricity meters and measuring devices give the significant values of the installation at all times: current, voltage, actual power, power consumption, in order to optimise the load factor.
Programmable time switches and programmers can be used to shift the operating ranges and "smooth out" consumption over time (operating factors).

${ }^{\wedge}$ Modular central

^ Electrical energy three-phase meter

## Distribution blocks (continued)

## LEGRAND DISTRIBUTION BLOCKS

The following installation possibilities and characteristics that have previously been described: rated current, short-circuit resistance, insulation values, number and capacities of outputs, connection method, enable the most suitable choice of distribution block to be determined.

The Legrand range of distribution blocks meets the needs of a wide variety of requirements, providing both ease of use and maximum safety.

Electrical characteristics of distribution blocks

| Type | Cat. Nos. | In (A) | $I^{2} t\left(A^{2} s\right)^{(1)}$ | Icw (kA) | Ipk (kÂ) | Ui (V) | Uimp (kV) |

## 1 INDEPENDENT DISTRIBUTION TERMINAL BLOCKS

Totally universal in their application, this type of terminal block can be used to distribute up to 100 A on between 4 and 33 outputs, depending on the catalogue number. The incoming cross-section is between 4 and $25 \mathrm{~mm}^{2}$, and the outputs between 4 and $16 \mathrm{~mm}^{2}$. They are fixed on $12 \times 2$ flat bars or TH $35-15$ and TH 35-7.5 rails.

## Independent distribution terminal blocks

^ Unprotected terminal blocks on supports are generally fixed on $12 \times 2$ flat bars for connecting protective conductors

^ Empty support for terminal blocks enables exactly the right number of connections to be created

${ }^{\wedge}$ Combining IP 2x terminal blocks and support Cat. No. 04810 enables a 2P, 3P or 4P distribution block to be created

< Fixed on $\_$or $\longleftarrow \square$ rail, the universal support Cat. No. 04811 takes all terminal blocks

## Distribution blocks (continued)

## 2 LEXIC SUPPLY BUSBARS

Supply busbars can be connected directly and supply power to Lexic modular devices up to 90 A . They are available in single, two, three and four pole versions. They are a flexible solution, taking up little space, and are easy to adapt for distribution in rows.

${ }^{\wedge}$ Supply busbar supplied via universal terminal Cat. No. 04906
${ }^{\wedge}$ Distribution via four pole supply busbar Cat. №. 04954 fitted with end protectors Cat. №. 04991

## 3 DISTRIBUTION TERMINALS

These single pole distribution blocks are fixed directly in the terminals of DPX 125, 160 and 250 ER devices and modular Vistop devices from 63 to 160 A. They are used for simplified distribution for panels where the number of main circuits is limited.

^ Six $35 \mathrm{~mm}^{2}$ rigid outputs ( $25 \mathrm{~mm}^{2}$ flexible) for the output terminal Cat. No. 04867

## 4 MODULAR DISTRIBUTION BLOCKS

These combine compactness and high connection capacity. With a modular profile, they are fixed by clipping onto TH 35-15 rails (EN 50022). Legrand modular distribution blocks are totally isolated: they are used at the supply end of the panel up to 250 A or in subgroups of outputs in panels with higher power ratings.

^ Totally universal, distribution blocks are suitable for all types of application

${ }^{\wedge}$ Single pole modular profile distribution blocks, total insulation of the poles to distribute 125 to 250 A

${ }^{\wedge}$ For the supply end of medium power distribution panels, the 250 A modular distribution block Cat. №. 04877 can also be fixed on a plate

## Distribution blocks (continued)

## 5 EXTRA-FLAT DISTRIBUTION BLOCKS

Their lower height and their current-carrying capacities mean that the same panel can manage the power requirements for the supply end lup to 250 A) combined with the compactness of modular rows in slim panels.

< The key features of extra-flat distribution blocks are power, capacity to connect large crosssection cables and compactness.

## 6 STEPPED DISTRIBUTION BLOCKS

These are available in catalogue versions, complete and fully-assembled from 125 to 400 A, and in a modular version (bars and supports to be ordered separately) that can be used to create customised distribution.

< 125 A stepped distribution block

^ 400 A stepped distribution block
$<250$ A distribution
blocks
Cat. No. 37435

## 7 SINGLE POLE ALUMINIUM/COPPER CONNECTION BOXES

Designed to provide the interface between large cross-section conductors entering the panel, including those made of aluminium, and internal wiring conductors.
Two models $120 \mathrm{~mm}^{2} / 70 \mathrm{~mm}^{2}$ (Cat. No. 374 80) and $300 \mathrm{~mm}^{2} / 185 \mathrm{~mm}^{2}$ (Cat. No. 374 81) are available. They can also be used for aluminium operating circuits loutgoing cables) or when the line lengths require the use of large crosssections.

Different connection configurations can be created by simply moving the cable clamp strips.

## 8 VIKING ${ }^{\text {TM }} 3$ POWER TERMINAL BLOCKS

These single pole blocks are used for the junction between the enclosure and the external cables. They are fixed on a $\_$rail or a plate and take CAB 3 and Duplix labelling. They provide numerous solutions for connection with aluminium or copper cables, with or without lugs.
